

System Resources Over Time (The Gauntlet)

Experiment Phase Breakdown

HARDWARE TELEMETRY & PERFORMANCE DIAGNOSTIC REPORT

Total Experiment Duration : 158 seconds
Starting Available Memory : 2274 MB
Ending Available Memory : 2577 MB

DIAGNOSIS & FINDINGS:

1. Human Noise Phase (Normal):
The system idled normally, capturing slight variations when apps were manually opened. The OS scheduler handled these spikes perfectly without starvation.
2. Synthetic CPU Starvation (Anomaly 1):
A stress-ng worker thread successfully locked a single CPU core, proving the telemetry sensor's ability to capture immediate, sharp bottleneck thresholds.
3. Organic Memory Leak (Anomaly 2):
A defective process aggressively consumed RAM. Unlike the CPU spike, this was a gradual slope. Available memory drained significantly until the process was terminated, proving the script can detect gradual software defects.

CONCLUSION:

The telemetry pipeline successfully isolated and documented three distinct operational states without crashing the host operating system.
